ABSTRACT. Let  $\mathcal{L}$  be a first-order two-sorted language. In general, very little model theory is possible if we restrict to  $\mathcal{L}$ -structures that have the form  $\langle M, I \rangle$  for some fixed structure  $I$ . But not everything is lost when  $I$  is a compact topological space. Continuous logic deals with this case. Revisiting old ideas we present a back-to-basics approach to continuous logic.

## 1. Introduction

As a minimal motivating example, consider a real vector space  $M$ . This is among the most simple structures considered in model theory. Now, expand it by adding a norm. A norm is a function that, given vector, outputs a real number. We may formalize this in a natural way by using a two-sorted structure  $\langle M, \mathbb{R} \rangle$ . Now, we have two conflicting aspirations

- i. to apply the basic tools of model theory (such as elementarity, compactness, and saturation);
- ii. to stay within the realm of normed spaces (hence insist that  $\mathbb{R}$  should remain  $\mathbb{R}$  throughout).

These two requests are blatantly incompatible, something has to give. Different people have attempted different paths.

1. Nonstandard analysts happily embrace norms that take values in some  ${}^*\mathbb{R} \geq \mathbb{R}$ . These normed spaces are nonstandard, but there are tricks to transfer results from nonstandard to standard normed spaces and vice versa. See [G] for a survey. Model theorists, when confronted with similar problems, have used similar approaches (in greater generality and with different notation).
2. Henson and Iovino propose to stick to the standard notion of norm but restrict the notion of elementarity and saturation to a smaller class of *positive* formulas. They demonstrate that most standard tools of model theory apply in their setting. The work of Henson and Iovino is focussed on Banach spaces and has hardly been applied to broader contexts. See [HI] for a survey.
3. Real valued logicians opt for an esoteric approach. They abandon classical true/false valued logic in favour of a logic valued in the interval  $[0, 1]$ . See [K] or [H] for a survey. This esoteric flavor helped the approach with some popularity but this approach adds unnatural notational burden. Our back-to-classical-logic approach is proposed as a more natural alternative.

We elaborate on the ideas of Henson and Iovino and generalize them to a larger class of structures. Following Henson and Iovino we restrict the notions of elementarity and saturation to positive formulas (though we use a larger class of positive formulas, which more convenient, and inessentially stronger). We also borrow intuitions and results from nonstandard analysis to an extent that we could claim the title: *nonstandard analysis for the standard logician*.

## 2. A class of structures

Let  $I$  be some fixed first-order structure which is endowed with a Hausdorff compact<sup>1</sup> topology (in particular, a normal topology). The language  $L_I$  contains relation symbols for the compact subsets  $C \subseteq I^n$

<sup>1</sup>The requirement of compactness seems to exclude the motivational example mentioned above. To include this and others similar examples we have to replace  $\mathbb{R}$  with  $\mathbb{R} \cup \{\pm\infty\}$ .

and a function symbol for each continuous functions  $f : I^n \rightarrow I$ . In particular, there is a constant for each element of  $I$ . According to the context,  $C$  and  $f$  denote either the symbols of  $L_I$  or their interpretation in the structure  $I$ . Such a language  $L_I$  is much larger than necessary but it is convenient because it uniquely associates a structure to a topological space.

The most straightforward examples of structures  $I$  are the unit interval  $[0, 1]$ , with the usual topology, and its homeomorphic copies  $\mathbb{R}^+ \cup \{0, \infty\}$  and  $\mathbb{R} \cup \{\pm\infty\}$ .

We also fix a first-order language  $L_H$  which we call the language of the **home sort**.

**Definition 1.** Let  $\mathcal{L}$  be a two sorted language that expands both  $L_H$  and  $L_I$ . By **model** we mean a two-sorted  $\mathcal{L}$ -structure of the form  $\langle M, I \rangle$ , where  $M$  ranges over all  $L_H$ -structures, while  $I$  is the structure we fixed above. We write **H** and **I** to denote the two sorts of  $\mathcal{L}$ .

The language  $\mathcal{L}$  adds a relation symbol for every  $L_H$ -definable subset of  $M$ , in other words,  $\mathcal{L}$  performs the Morleyzation of  $L_H$ .

Finally and most relevantly,  $\mathcal{L}$  contains arbitrarily many function symbols of sort  $H^n \rightarrow I$ .

Models are denoted by the domain of their home sort.

The notion of model will be (inessentially) restricted once the monster model is introduced in Section 7.

Clearly, saturated  $\mathcal{L}$ -structures exist but, with the exception of trivial cases (when  $I$  is finite), they are not models in the sense of Definition 1. As a remedy, below we carve out a set of formulas  $\mathcal{L}^P$ , the set of positive formulas, such that every model has an positive elementary saturated extension that is also a model.

As usual,  $L_I$ ,  $L_H$ , and  $\mathcal{L}$  denote both first-order languages and the corresponding set of formulas. When we restrict to formulas with a fix tuple of free variables we write  $\mathcal{L}_x$ .

**Definition 2.** A formula in  $\mathcal{L}$  is **positive** if it uses only the Boolean connectives  $\wedge, \vee$ ; the quantifiers  $\forall^H, \exists^H$  of sort H; and the quantifiers  $\forall^I, \exists^I$  of sort I.

The set of positive formulas is denoted by  $\mathcal{L}^P$ .

We will use Latin letters  $x, y, z$  for variables of sort H and Greek letters  $\eta, \varepsilon$  for variables of sort I. Therefore we can safely drop the superscript from quantifiers if they are followed by variables.

Note that  $\mathcal{L}$  has two sorts of atomic formulas: those of sort H (that is, those equivalent to formulas in  $L_H$ ) and those of the form  $t(x; \eta) \in C$ , where  $C \subseteq I^n$  is compact and  $t(x; \eta)$  is a tuple of terms of sort  $H^{|x|} \times I^{|\eta|} \rightarrow I$ .

Henson and Iovino have a more stringent notion of positive formulas (that they define in the language of normed spaces). Their positive formulas exclude formulas in  $L_H$  and quantifiers of sort I. In our setting  $L_H$ -formulas are positive (up to equivalence) which comes at a small price: the failure of the Perturbation Lemma [HI, Proposition 5.15]. However, we will recover part of it in Proposition 33. Instead, somewhat surprisingly, allowing quantifiers of sort I is almost for free. We will see (cf. Propositions 27) that the formulas in  $\mathcal{L}^P$  are approximated by formulas without quantifiers of sort I.

Note that the extra expressivity offered by quantifiers of sort I is convenient. For instance, it is easy to see (cf. Example 3 for a hint) that  $\mathcal{L}^P$  has at least the same expressive power as real valued logic

**Example 3.** Let  $I = [0, 1]$ , the unit interval in  $\mathbb{R}$ . Let  $t(x)$  be a term of sort  $H^{|x|} \rightarrow I$ . Then there is a positive formula that says  $\sup_x t(x) = \tau$ . Indeed, consider the formula

$$\forall x [t(x) \dot{-} \tau \in \{0\}] \quad \wedge \quad \forall \varepsilon [\varepsilon \in \{0\} \vee \exists x [\tau \dot{-} (t(x) + \varepsilon) \in \{0\}]]$$

which, in a more legible form, becomes

$$\forall x [t(x) \leq \tau] \quad \wedge \quad \forall \varepsilon > 0 \exists x [\tau \leq t(x) + \varepsilon].$$

The following example is inspired by [HPP].

**Example 4.** Let  $\mathcal{U}$  be a monster model of signature  $L_H$ . The relevant part of  $\mathcal{L}$  contains symbols for the functions  $f: \mathcal{U}^n \rightarrow I$  that are continuous in the following sense: the inverse image of every compact  $C \subseteq I$  is type-definable in  $L_H(M)$  for every  $M \leq \mathcal{U}$ . It is easy to verify that the model  $\langle \mathcal{U}, I \rangle$  is positively saturated, see definition in Section 6.

We mentioned normed spaces as a motivating example. Essentially, functional analysis and model theory are only interested in the unit ball of normed spaces. To formalize the unit ball of a normed space as a model (where  $I$  is the unit interval) is straightforward but pretty ugly. Alternatively one can view a normed space as a many-sorted structure: a sort for each ball of radius  $n \in \mathbb{Z}^P$ . Unfortunately, this also results into a bloated formalism.

A neater formalization is possible if one accepts that some positive elementary extensions (to be defined below) of a normed space could contain vectors of infinite norm hence not be themselves normed spaces. These infinities are harmless if one is only interested in the unit ball. In fact, inside any ball of finite radius these nonstandard normed spaces are completely standard.

**Example 5.** Let  $I = \mathbb{R} \cup \{\pm\infty\}$ . Let  $L_H$  be the language of real (or complex) vector spaces. The language  $\mathcal{L}$  contains a function symbol  $\|\cdot\|$  of sort  $H \rightarrow I$ . Normed space are models with the natural interpretation of the language. It is easy to verify that the unit ball of every model is a the unit ball of a normed space. Note that the same remains true if we add to the language any continuous (equivalently, bounded) operator or functional.

We conclude this introduction with a question. Is it possible to extend the Compactness Theorem 19 to a larger class of formulas? E.g. can we allow in  $\mathcal{L}$  (and in  $\mathcal{L}^P$ ) function symbols of sort  $H^n \times I^m \rightarrow I$  with both  $n$  and  $m$  positive? These would have natural interpretations, e.g. a group acting on a compact set  $I$ .

### 3. Henson-Iovino approximations

For  $\varphi, \varphi'$  (free variables are hidden) positive formulas possibly with parameters we write  $\varphi' > \varphi$  if  $\varphi'$  is obtained by replacing in  $\varphi$  each atomic formula of the form  $t \in C$  with  $t \in C'$ , where  $C'$  is some compact neighborhood of  $C$ . If no such atomic formulas occurs in  $\varphi$ , then  $\varphi > \varphi$ . We call  $\varphi'$  a **weakening** of  $\varphi$ . Note that  $>$  is a dense transitive relation and that  $\varphi \rightarrow \varphi'$  in every  $\mathcal{L}$ -structure.

We write  $\tilde{\varphi} \perp \varphi$  when  $\tilde{\varphi}$  is obtained by replacing each atomic formula  $t \in C$  occurring in  $\varphi$  with  $t \in \tilde{C}$  where  $\tilde{C}$  is some compact set disjoint from  $C$ . The atomic formulas in  $L_H$  are replaced with their negation. Finally each connective is replaced by its dual i.e.,  $\vee, \wedge, \exists, \forall$  are replaced by  $\wedge, \vee, \forall, \exists$ , respectively. We say that  $\tilde{\varphi}$  is a **strong negation** of  $\varphi$ . It is clear that  $\tilde{\varphi} \rightarrow \neg\varphi$  in every  $\mathcal{L}$ -structure.

**Lemma 6.** For all positive formulas  $\varphi$

1. for every  $\varphi' > \varphi$  there is a formula  $\tilde{\varphi} \perp \varphi$  such that  $\varphi \rightarrow \neg\tilde{\varphi} \rightarrow \varphi'$ ;
2. for every  $\tilde{\varphi} \perp \varphi$  there is a formula  $\varphi' > \varphi$  such that  $\varphi \rightarrow \varphi' \rightarrow \neg\tilde{\varphi}$ .

*Proof.* If  $\varphi \in L_H$  the claims are obvious. Suppose  $\varphi$  is of the form  $t \in C$ . Let  $\varphi'$  be  $t \in C'$ , for some compact neighborhood of  $C$ . Let  $O$  be an open set such that  $C \subseteq O \subseteq C'$ . Then  $\tilde{\varphi} = (t \in I \sim O)$  is as required by the lemma. Suppose instead that  $\tilde{\varphi}$  is of the form  $t \in \tilde{C}$  for some compact  $\tilde{C}$  disjoint from  $C$ . By the normality of  $I$ , there is  $C'$ , a compact neighborhood of  $C$  disjoint from  $\tilde{C}$ . Then  $\varphi' = (t \in C')$  is as required. The lemma follows easily by induction.  $\square$

For every type  $p(x)$ , we write

$$p'(x) = \{\varphi'(x) : \varphi' > \varphi \text{ for some } \varphi(x) \in p\}$$

in particular  $\{\varphi(x)\}' = \{\varphi'(x) : \varphi' > \varphi\}$ .

**Definition 7.** A set of formulas  $\mathcal{F} \subseteq \mathcal{L}$  is **dense** if for every positive  $\varphi(x)$  and every  $\varphi' > \varphi$ , there is  $\psi(x) \in \mathcal{F}$  such that  $\varphi(x) \rightarrow \psi(x) \rightarrow \varphi'(x)$  hold in every model.

If these implications holds in every model of  $T$  we say that  $\mathcal{F}$  is dense modulo  $T$ .

**Example 8.** By Lemma 6, the set of negations of positive formulas is dense.

**Example 9.** Read  $\alpha = \beta$  as synonymous of  $\langle \alpha, \beta \rangle \in \Delta$ , where  $\Delta$  is the diagonal of  $I^2$ , a compact set. It is easy to see that the set of formulas build inductively from the atomic formulas of sort  $H$  and  $t(x) = s(x)$  is dense.

**Example 10.** Let  $\mathcal{H}$  be the set of positive formulas without quantifiers of sort  $I$ . In Section 8 we will prove that this set is dense. Interestingly this set is closed under weakening and strong negation.

#### 4. Morphisms

Let  $M$  and  $N$  be two models. We say that a partial map  $f : M \rightarrow N$  is **p-elementary** if for every  $\varphi(x) \in \mathcal{L}^P$  and every  $a \in (\text{dom } f)^{|x|}$

$$1. \quad M \models \varphi(a) \Rightarrow N \models \varphi(fa).$$

A p-elementary map that is total is called an **p-elementary embedding**. When the map  $\text{id}_M : M \rightarrow N$  is an p-elementary embedding, we write  $M \leq^P N$  and say that  $M$  is an **p-elementary submodel** of  $N$ .

As  $\mathcal{L}^P$  are in particular  $L_H$ -elementary, they are injective. However, their inverse need not be p-elementary. In other words, the converse of the implication in (1) may not hold. Hence the following notion of elementarity which is more robust. We say that the map  $f : M \rightarrow N$  is an **approximate p-elementary** if for every formula  $\varphi(x) \in \mathcal{L}^P$ , and every  $a \in (\text{dom } f)^{|x|}$

$$2. \quad M \models \varphi(a) \Rightarrow N \models \{\varphi(fa)\}'.$$

One convenient feature of approximate p-elementarity is that for it to hold it suffices verify (2) for any/some dense set of formulas. It is clear that p-elementarity implies its approximate variant. We will see that with a slight amount of saturation also the converse holds (Proposition 21). Finally, under full saturation, all differences disappear as all these morphisms becomes  $\mathcal{L}$ -elementarity maps (Corollary 26).

The following holds in general.

**Fact 11.** If  $f : M \rightarrow N$  is approximate p-elementary then

$$M \models \{\varphi(a)\}' \Leftrightarrow N \models \{\varphi(fa)\}'.$$

for every  $\varphi(x) \in \mathcal{L}^P$ , and every  $a \in (\text{dom } f)^{|x|}$ .

*Proof.*  $\Rightarrow$  Fix  $\varphi' > \varphi$  and assume  $M \models \varphi'(a)$ . Let  $\varphi' > \varphi'' > \varphi$ . By the definition of approximate elementarity,  $N \models \varphi''(fa)$  and  $N \models \varphi'(fa)$  follows.

$\Leftarrow$  Assume the r.h.s. of the equivalence. Fix  $\varphi' > \varphi$  and prove  $M \models \varphi'(a)$ . Let  $\varphi' > \varphi'' > \varphi$ . By Lemma 6 there is some  $\tilde{\varphi} \perp \varphi''$  such that  $\varphi'' \rightarrow \neg \tilde{\varphi} \rightarrow \varphi'$ . Then  $N \models \neg \tilde{\varphi}(fa)$  and therefore  $M \models \neg \tilde{\varphi}(a)$ . Then  $M \models \varphi'(a)$ .  $\square$

Finally, we consider the notion of partial embeddings. Though the definition seems weaker, we prove that the notion is completely classical. We say that the map  $f : M \rightarrow N$  is a **partial embedding** if the implication in (1) holds for all atomic formulas  $\varphi(x)$ . Note that this is the same as requiring that (1) holds for all formulas without quantifiers of sort  $H$ .

**Fact 12.** If  $f : M \rightarrow N$  is a partial embedding then

$$M \models \varphi(a) \Leftrightarrow N \models \varphi(fa)$$

for every  $a \in (\text{dom } f)^{|x|}$  and every formula  $\varphi(x) \in \mathcal{L}^P$  without quantifiers of sort  $H$ .

*Proof.* The equivalence is trivial for formulas in  $L_H$  so we only consider atomic formulas of the form  $t \in C$ . Implication  $\Rightarrow$  holds by definition. Vice versa, if  $M \models t(a) \notin C$  then, by normality,  $M \models t(a) \in \tilde{C}$  for some compact  $\tilde{C}$  disjoint of  $C$ . By the definition of partial embedding,  $N \models t(a) \in \tilde{C}$ . Hence  $N \models t(a) \notin C$ . Induction is immediate.  $\square$

## 5. The standard part

Our goal is to prove the Compactness Theorem for positive theories. To bypass lengthy applications of ultrafilters, ultrapowers, and ultralimits, we assume the Classical Compactness Theorem and built on that.

In this section we recall the notion of standard part of an element of the elementary extension of a compact Hausdorff topological space. Our goal is to prove Lemma 17 which in turn is required for the proof of the Positive Compactness Theorem (Theorem 19). The reader willing to accept it without proof may skip this section.

Let  $\langle N, *I \rangle$  be an  $\mathcal{L}$ -structure that extends  $\mathcal{L}$ -elementarily the model  $M$ . Let  $\eta$  be a free variable of sort  $I$ . For each  $\beta \in I$ , we define the type

$$m_\beta(\eta) = \{\eta \in D : D \text{ compact neighborhood of } \beta\}.$$

The set of the realizations of  $m_\beta(\eta)$  in  $*I$  is known to nonstandard analysts as the monad of  $\beta$ . The following fact is well-known.

**Fact 13.** For every  $\alpha \in *I$  there is a unique  $\beta \in I$  such that  $*I \models m_\beta(\alpha)$ .

*Proof.* Negate the existence of  $\beta$ . For every  $\gamma \in I$  pick some compact neighborhood  $D_\gamma$  of  $\gamma$ , such that  $*I \models \alpha \notin D_\gamma$ . By compactness there is some finite  $\Gamma \subseteq I$  such that  $D_\gamma$ , with  $\gamma \in \Gamma$ , cover  $I$ . By elementarity these  $D_\gamma$  also cover  $*I$ . A contradiction. The uniqueness of  $\beta$  follows from normality.  $\square$

We denote by  $\text{st}(\alpha)$  the unique  $\beta \in I$  such that  $*I \models m_\beta(\alpha)$ .

**Fact 14.** For every  $\alpha \in {}^*I$  and every compact  $C \subseteq I$

$${}^*I \models \alpha \in C \rightarrow \text{st}(\alpha) \in C.$$

*Proof.* Assume  $\text{st}(\alpha) \notin C$ . By normality there is a compact set  $D$  disjoint from  $C$  that is a neighborhood of  $\text{st}(\alpha)$ . Then  ${}^*I \models \alpha \in D \subseteq \neg C$ .  $\square$

**Fact 15.** For every  $\alpha \in ({}^*I)^{|\alpha|}$  and every function symbol  $f$  of sort  $|\alpha| \rightarrow I$

$${}^*I \models \text{st}(f(\alpha)) = f(\text{st}(\alpha)).$$

*Proof.* By Fact 13 and the definition of  $\text{st}(-)$  it suffices to prove that  ${}^*I \models f(\alpha) \in D$  for every compact neighborhood  $D$  of  $f(\text{st}(\alpha))$ .

Fix one such  $D$ . Then  $\text{st}(\alpha) \in f^{-1}[D]$ . By continuity  $f^{-1}[D]$  is a compact neighborhood of  $\text{st}(\alpha)$ . Therefore  ${}^*I \models \alpha \in f^{-1}[D]$  and, as  $I \leq {}^*I$  we obtain  ${}^*I \models f(\alpha) \in D$ .  $\square$

The standard part of  $\langle N, {}^*I \rangle$  is the model  $\langle N, I \rangle$  that interprets the symbols  $f$  of sort  $H^n \rightarrow I$  as the functions

$$f^N(a) = \text{st}({}^*f(a)) \quad \text{for all } a \in N^n,$$

where  ${}^*f$  is the interpretation of  $f$  in  $\langle N, {}^*I \rangle$ . Symbols in  $L_H$  maintain the same interpretation.

**Fact 16.** With the notation as above. Let  $t(x; \eta)$  be a term of sort  $H^{|\alpha|} \times I^{|\eta|} \rightarrow I$ . Then for every  $a \in M^{|\alpha|}$  and  $\alpha \in ({}^*I)^{|\eta|}$

$$t^N(a; \text{st}(\alpha)) = \text{st}({}^*t(a; \alpha))$$

*Proof.* When  $t$  is a function symbol of sort  $H^{|\alpha|} \rightarrow I$ , the claim holds by definition. When  $t$  is a function symbol of sort  $I^{|\eta|} \rightarrow I$ , the claim follows from Fact 15. Now, assume inductively that

$$t_i^N(a; \text{st}(\alpha)) = \text{st}({}^*t_i(a; \alpha))$$

holds for the terms  $t_1(x; \eta), \dots, t_n(x; \eta)$  and let  $t = f(t_1, \dots, t_n)$  for some function  $f$  of sort  $I^n \rightarrow I$ . Then the claim follows immediately from the induction hypothesis and Fact 15.  $\square$

**Lemma 17.** With the notation as above. For every  $\varphi(x; \eta) \in \mathcal{L}^P$ ,  $a \in N^{|\alpha|}$  and  $\alpha \in ({}^*I)^{|\eta|}$

$$\langle N, {}^*I \rangle \models \varphi(a; \alpha) \Rightarrow N \models \varphi(a; \text{st}(\alpha))$$

*Proof.* Suppose  $\varphi(x; \eta)$  is  $\mathcal{L}^P$ -atomic. If  $\varphi(x; \eta)$  is a formula of  $L_H$  the claim is trivial. Otherwise  $\varphi(x; \eta)$  has the form  $t(x; \eta) \in C$ . Assume that the tuple  $t(x; \eta)$  consists of a single term. The general case follows easily from this special case. Assume that  $\langle N, {}^*I \rangle \models t(a; \alpha) \in C$ . Then  $\text{st}({}^*t(a; \alpha)) \in C$  by Fact 14. Therefore  $t^N(a; \text{st}(\alpha)) \in C$  follows from Fact 16. This proves the lemma for atomic formulas. Induction is immediate.  $\square$

**Corollary 18.** Let  $M$  be an arbitrary model. Let  $p(\eta) \subseteq \mathcal{L}^P(M)$  be a type that does not contain existential quantifiers of sort  $H$ . Then, if  $p(\eta)$  is finitely consistent in  $M$ , it is realized in  $M$ .

The corollary has also a direct proof. This goes through the observation that the formulas in  $p(\eta)$  define compact subsets of  $I$ .

*Proof.* Let  $\langle *M, *I \rangle$  be an  $\mathcal{L}$ -elementary saturated superstructure of  $\langle M, I \rangle$ . Then  $\langle *M, *I \rangle \models p(\alpha)$  for some  $\alpha \in *I$ . By the lemma above,  $*M \models p(\text{st}(\alpha))$ . Now observe that the truth of formulas without existential quantifiers of sort  $H$  is preserved by substructures.  $\square$

The exclusion of existential quantifiers of sort  $H$  is necessary. For a counterexample take  $M = I = [0, 1]$ . Assume that  $\mathcal{L}$  contains a function symbol for the identity map  $\iota : M \rightarrow I$ . Let  $p(\eta)$  contain the formulas  $\exists x (x > 0 \wedge \iota x + \eta \in [0, 1/n])$  for all positive integers  $n$ .

## 6. Compactness

It is convenient to distinguish between consistency with respect to models and consistency with respect to  $\mathcal{L}$ -structures. We say that a theory  $T$  is  $\mathcal{L}$ -consistent when  $\langle M, *I \rangle \models T$  for some  $\mathcal{L}$ -structure. We say that  $T$  is consistent when  $M \models T$  is for some model  $M$ .

**Theorem 19 (Positive Compactness Theorem).** Let  $T$  be a positive theory that is finitely  $\mathcal{L}$ -consistent. Then  $T$  is consistent.

*Proof.* Suppose  $T$  is finitely  $\mathcal{L}$ -consistent. By the classical Compactness Theorem, there is an  $\mathcal{L}$ -structure  $\langle M, *I \rangle \models T$ . Let  $\langle M, I \rangle$  be its standard part as defined in Section 5. Then  $M \models T$  by Lemma 17.  $\square$

A model  $N$  is **positively  $\lambda$ -saturated** if it realizes all types  $p(x; \eta) \subseteq \mathcal{L}^P(N)$  with fewer than  $\lambda$  parameters that are finitely consistent in  $N$ . When  $\lambda = |N|$  we simply say **positively saturated**. The existence of positively saturated models is obtained from the classical case just as for Theorem 19.

**Theorem 20.** Every model has an  $p$ -elementary extension to a positively saturated model (possibly of inaccessible cardinality).

The following proposition shows that a slight amount of saturation tames the positive formulas.

**Proposition 21.** Let  $N$  be a positively  $\omega$ -saturated model. Then

$$\{\varphi(x; \eta)\}' \leftrightarrow \varphi(x; \eta)$$

holds in  $N$  for every formula  $\varphi(x; \alpha) \in \mathcal{L}^P(N)$ .

*Proof.* We prove  $\rightarrow$ , the non trivial implication. The claim is clear for atomic formulas. Induction for conjunction, disjunction and the universal quantifiers is immediate. We consider case of the existential quantifiers of sort  $H$ . Assume inductively

$$\text{ih.} \quad \{\varphi(x, z; \eta)\}' \rightarrow \varphi(x, z; \eta)$$

We need to prove

$$\{\exists z \varphi(x, z; \eta)\}' \rightarrow \exists z \varphi(x, z; \eta)$$

From (ih) we have

$$\exists z \{\varphi(x, z; \eta)\}' \rightarrow \exists z \varphi(x, z; \eta)$$

Therefore it suffices to prove

$$\{\exists z \varphi(x, z; \eta)\}' \rightarrow \exists z \{\varphi(x, z; \eta)\}'$$

Replace the variables  $x; \eta$  with parameters, say  $a; \alpha$  and assume that the theory  $\{\exists z \varphi'(a, z; \alpha) : \varphi' > \varphi\}$  is true in  $N$ . We need to prove the consistency of the type  $\{\varphi'(a, z; \alpha) : \varphi' > \varphi\}$ . By saturation, finite consistency suffices. This is clear if we show that the antecedent is closed under conjunction. Indeed it

is easy to verify that if  $\varphi_1, \varphi_2 > \varphi$  then  $\varphi_1 \wedge \varphi_2 > \varphi'$  for some  $\varphi' > \varphi$ . In words, the set of approximations of  $\varphi$  is a directed set.

For existential quantifiers of sort  $\mathbf{l}$  we argue similarly.  $\square$

By Corollary 18, when  $\varphi(x; \eta)$  does not contains existential quantifiers of sort  $\mathbf{H}$ , the proposition above does not require the assumption of saturation. In general, some saturation is necessary: consider the model presented after Corollary 18 and the formula  $\exists x (x > 0 \wedge \iota(x) \in \{0\})$ .

A consequence of Proposition 21 is that the approximate morphisms defined in Section 4 coincide with their unapproximate version when the codomain is a positively  $\omega$ -saturated model.

## 7. The monster model

We denote by  $\mathcal{U}$  some large positively saturated model which we call the **monster model**. Truth is evaluated in  $\mathcal{U}$  unless otherwise is specified. Below we say **model** for  $\mathbf{p}$ -elementary submodel of  $\mathcal{U}$ . We stress once again that the truth of some  $\varphi \in \mathcal{L}^{\mathbf{p}}(M)$  in a model  $M$  implies the truth of  $\varphi$  (in  $\mathcal{U}$ ) but not vice versa. If also the converse implication holds we say  $M$  a **strong model**. However, all models agree on the approximated truth, see Fact 11,

$$M \models \{\varphi\}' \Leftrightarrow \{\varphi\}'$$

Hence strong models are those that realize the equivalence in Proposition 21, e.g. positively  $\omega$ -saturated models are strong models.

The following fact demonstrates how positive compactness applies. There are some subtle differences from the classical setting.

**Fact 22.** Let  $p(x) \subseteq \mathcal{L}^{\mathbf{p}}(A)$  be a type. Then for every  $\varphi(x) \in \mathcal{L}^{\mathbf{p}}(\mathcal{U})$

1. if  $p(x) \rightarrow \neg\varphi(x)$  then  $\psi(x) \rightarrow \neg\varphi(x)$  for some  $\psi(x)$  conjunction of formulas in  $p(x)$ ;
2. if  $p(x) \rightarrow \varphi(x)$  and  $\varphi' > \varphi$  then  $\psi(x) \rightarrow \varphi'(x)$  for some conjunction of formulas in  $p(x)$ .

*Proof.* (1) is immediate by saturation; (2) follows from (1) by Lemma 6.  $\square$

When  $A \subseteq \mathcal{U}$ , we write  $S_x^{\mathbf{p}}(A)$  for the set of maximally consistent subsets of  $\mathcal{L}_x^{\mathbf{p}}(A)$ . We define **p-tp( $a/A$ )**, the positive type of  $a$  over  $A$ , to be the set of formulas  $\{\varphi(x) \in \mathcal{L}^{\mathbf{p}}(A) : \varphi(a)\}$ . In general, if  $\mathcal{F}$  is any set of formulas, we write  **$\mathcal{F}$ -tp( $a/A$ )**, for the type  $\{\varphi(x) \in \mathcal{F}(A) : \varphi(a)\}$ .

**Fact 23.** Let  $p(x) \subseteq \mathcal{L}^{\mathbf{p}}(A)$ . The following are equivalent

1.  $p(x)$  is a maximally consistent subsets of  $\mathcal{L}_x^{\mathbf{p}}(A)$ ;
2.  $p(x) = \mathbf{p}\text{-tp}(a/A)$  for some  $a \in \mathcal{U}^{|x|}$ .

*Proof.* (1 $\Rightarrow$ 2) By the saturation of  $\mathcal{U}$ , there is an  $a \in \mathcal{U}^{|x|}$  such that  $p(x) \subseteq \mathbf{p}\text{-tp}(a/A)$ . By maximality  $p(x) = \mathbf{p}\text{-tp}(a/A)$ .

(2 $\Rightarrow$ 1) From Lemma 6 and Proposition 21 we obtain

$$\neg\varphi(x) \rightarrow \bigvee_{\tilde{\varphi} \perp \varphi} \tilde{\varphi}(x).$$

Suppose  $\varphi(x) \in \mathcal{L}^{\mathbf{p}}(A) \sim p$ . Then  $\neg\varphi(a)$ . Hence  $\tilde{\varphi}(a)$  holds for some  $\tilde{\varphi} \perp \varphi$  and  $p(x) \rightarrow \neg\varphi(x)$  follows.  $\square$

Let  $\mathcal{H}$  be the set of positive formulas without quantifiers of sort  $\mathbf{l}$ . Note that in the proof above we could replace  $\mathcal{L}^{\mathbf{p}}$  with any class of positive formulas closed under strong negation. Therefore we can also claim the following.

**Fact 24.** Let  $p(x) \subseteq \mathcal{H}(A)$ . The following are equivalent

1.  $p(x)$  is a maximally consistent subset of  $\mathcal{H}_x(A)$ ;
2.  $p(x) = \mathcal{H}\text{-tp}(a/A)$  for some  $a \in \mathcal{U}^{|x|}$ .

## 8. Elimination of quantifiers of sort I

We show that the quantifiers of sort I can be eliminated up to some approximation. Precisely, we prove that the set formulas  $\mathcal{H}$  defined above is dense, see Definition 7.

We say that partial map  $f : \mathcal{U} \rightarrow \mathcal{U}$  is  $\mathcal{H}$ -elementary if it preserves the truth of formulas in  $\mathcal{H}$ .

**Proposition 25.** Every  $\mathcal{H}$ -elementary map of cardinality  $< |\mathcal{U}|$  extends to an automorphism of  $\mathcal{H}$ .

*Proof.* By Fact 24, the inverse of an  $\mathcal{H}$ -elementary map is also  $\mathcal{H}$ -elementary. Then we can extend the map by back-and-forth as usual.  $\square$

Let  $A \subseteq \mathcal{U}$  be a small set throughout this section. We apply the proposition above to obtain a strengthening of Fact 24. For  $a, b \in \mathcal{U}^{|x|}$  we write  $a \equiv_A b$  if  $a$  and  $b$  satisfy the same  $\mathcal{L}$ -formulas over  $A$ .

**Corollary 26.** Let  $p(x) \subseteq \mathcal{H}(A)$ . The following are equivalent

1.  $p(x)$  is a maximally consistent subsets of  $\mathcal{H}_x(A)$ ;
2.  $p(x) \leftrightarrow q(x) = \text{tp}(a/A)$  for some  $a \in \mathcal{U}^{|x|}$ .

*Proof.* (2 $\Rightarrow$ 1) Clear.

(1 $\Rightarrow$ 2) If  $b \models p(x) = \mathcal{H}\text{-tp}(a/A)$  then there is an  $\mathcal{H}$ -elementary map  $f \supseteq \text{id}_A$  such that  $fa = b$ . Then  $f$  extends to an automorphism. As every automorphism is  $\mathcal{L}$ -elementary,  $a \equiv_A b$ , and (2) follows.  $\square$

In the classical setting, from an equivalence between types one derives an equivalence between formulas. Without negation, this is not true. Still, we can infer an approximate form of equivalence.

**Proposition 27.** The set  $\mathcal{H}$  is dense.

*Proof.* Let  $\varphi(x)$  be a positive formula. We need to prove that for every  $\varphi' > \varphi$  there is some  $\psi(x) \in \mathcal{H}$  such that  $\varphi(x) \rightarrow \psi(x) \rightarrow \varphi'(x)$ . By Corollary 26 and Proposition 21

$$\neg\varphi(x) \rightarrow \bigvee_{p'(x) \rightarrow \neg\varphi(x)} p'(x)$$

where  $p(x)$  ranges over the maximally consistent  $\mathcal{H}$ -types. By Fact 22 and Lemma 6

$$\neg\varphi(x) \rightarrow \bigvee_{\neg\tilde{\psi}(x) \rightarrow \neg\varphi(x)} \neg\tilde{\psi}(x),$$

where  $\tilde{\psi}(x) \in \mathcal{H}$ . Equivalently,

$$\varphi(x) \leftarrow \bigwedge_{\tilde{\psi}(x) \leftarrow \varphi(x)} \tilde{\psi}(x).$$

By compactness, see Fact 22, for every  $\varphi' > \varphi$  there are some finitely many  $\tilde{\psi}_i(x) \in \mathcal{H}$  such that

$$\varphi'(x) \leftarrow \bigwedge_{i=1, \dots, n} \tilde{\psi}_i(x) \leftarrow \varphi(x)$$

which yields the interpolant required by the proposition.  $\square$

**Proposition 28.** Let  $\mathcal{F}$  be a dense set of positive formulas. Then for every  $\varphi(x) \in \mathcal{L}$

$$\varphi(x) \leftrightarrow \bigvee \{\psi(x) \in \mathcal{F} : \psi'(x) \rightarrow \varphi(x)\}.$$

*Proof.* Only  $\rightarrow$  requires a proof. Let  $a \in \mathcal{U}^{[x]}$  be such that  $\varphi(a)$ . Let  $p(x) = \mathcal{H}\text{-tp}(a/A)$ . Recall that  $p(x) \leftrightarrow p'(x)$  for all  $p(x) \in \mathcal{L}^p$ . By Corollary 26,  $p(x) \rightarrow \varphi(x)$ . As  $\mathcal{F}$  is dense,  $p'(x) \leftrightarrow q(x) = \mathcal{F}\text{-tp}(a/A)$ . Then  $q'(x) \rightarrow \varphi(x)$  and, by compactness,  $\psi'(x) \rightarrow \varphi(x)$  for some  $\psi'(x) \in q'$ .  $\square$

### 9. The Tarski-Vaught test and the Löwenheim-Skolem theorem

The following proposition is our equivalent to the Tarski-Vaught test.

**Proposition 29.** Let  $M$  be a subset of  $\mathcal{U}$ . Let  $\mathcal{F}$  be a dense set of positive formulas. Then the following are equivalent

1.  $M$  is a model;
2. for every formula  $\psi(x) \in \mathcal{F}(M)$ 

$$\exists x \psi(x) \Rightarrow \text{for every } \psi' > \psi \text{ there is an } a \in M \text{ such that } \psi'(a);$$
3. for every formula  $\psi(x) \in \mathcal{F}(M)$ 

$$\exists x \neg \psi(x) \Rightarrow \text{there is an } a \in M \text{ such that } \neg \psi(a).$$

*Proof.* (1 $\Rightarrow$ 2) Assume  $\exists x \psi(x)$  and let  $\psi' > \psi$  be given. By Lemma 6 there is some  $\tilde{\psi} \perp \psi$  such that  $\psi(x) \rightarrow \neg \tilde{\psi}(x) \rightarrow \psi'(x)$ . Then  $\neg \forall x \tilde{\psi}(x)$  hence, by (1),  $M \models \neg \forall x \tilde{\psi}(x)$ . Then  $M \models \neg \tilde{\psi}(a)$  for some  $a \in M$ . Hence  $M \models \psi'(a)$  and  $\psi'(a)$  follows from (1).

(2 $\Rightarrow$ 3) Assume (2) and let  $\psi(x) \in \mathcal{F}(M)$  be such that  $\exists x \neg \psi(x)$ . By Proposition 30, there are a consistent  $\varphi(x) \in \mathcal{F}(M)$  and some  $\varphi' > \varphi$  such that  $\varphi'(x) \rightarrow \neg \psi(x)$ . Then (3) follows.

(2 $\Rightarrow$ 1) Assume (2). By the classical Tarski-Vaught test  $M \preceq_{\mathcal{H}} \mathcal{U}$ . Then  $M$  is the domain of an  $\mathcal{L}$ -substructure of  $\mathcal{U}$ . Then  $\varphi(a) \Leftrightarrow M \models \varphi(a)$  holds for every atomic formula  $\varphi(x)$  and for every  $a \in M^{[x]}$ . Now, assume inductively

$$M \models \varphi(a, b) \Rightarrow \varphi(a, b).$$

Using (2) and the induction hypothesis we prove by contraposition that

$$M \models \forall y \varphi(a, y) \Rightarrow \forall y \varphi(a, y).$$

Indeed,

$$\begin{aligned} \neg \forall y \varphi(a, y) &\Rightarrow \exists y \neg \varphi(a, y) \\ &\Rightarrow \exists y \neg \varphi'(a, y) && \text{for some } \varphi' > \varphi \\ &\Rightarrow \exists y \neg \psi(a, y) && \text{for some } \psi \in \mathcal{F} \text{ such that } \varphi(a, y) \rightarrow \psi(a, y) \rightarrow \varphi'(a, y) \\ &\Rightarrow \neg \psi(a, b) && \text{for some } b \in M \text{ by (2)} \\ &\Rightarrow \neg \varphi(a, b) \\ &\Rightarrow M \models \neg \varphi(a, b) && \text{by induction hypothesis} \\ &\Rightarrow M \not\models \forall y \varphi(a, y). \end{aligned}$$

Induction for the connectives  $\vee, \wedge, \exists^H, \exists$ , and  $\forall^I$  is straightforward.  $\square$

Classically, the main application of the Tarski-Vaught test is in the proof of the downward Löwenheim-Skolem Theorem. Note that here the classical downward Löwenheim-Skolem Theorem holds in full for all  $\mathcal{L}$ -structures. In particular every  $A \subseteq \mathcal{U}$  is contained in a model of cardinality  $|\mathcal{L}(A)|$ . In this form the

Löwenheim-Skolem Theorem is not very informative. In fact, the cardinality of  $\mathcal{L}$  is excessively large because of the abundance of symbols in  $L_I$ .

We say that  $\mathcal{L}$  is **separable** if there is a countable dense set  $\mathcal{F}$  of positive formulas.

**Proposition 30.** Assume that  $\mathcal{L}$  is separable. Let  $A \subseteq \mathcal{U}$  be countable. Then there is a countable model  $M$  containing  $A$ .

*Proof.* As in the classical proof of the Löwenheim-Skolem Theorem, we construct  $M \subseteq \mathcal{U}$  that contain a witness for every consistent formula in  $\mathcal{F}(M)$ . By separability and Proposition 29,  $M$  is a model.  $\square$

We have defined separability as a property of  $\mathcal{L}$ . Arguably, it could have been introduced as a property of the theory of  $\mathcal{U}$ . The following proposition provides the examples that motivate the definition of separability (in these examples the property depends solely on  $\mathcal{L}$ ).

**Proposition 31.** Assume that  $L_H$  is countable and that  $\mathcal{L}$  has at most countably many symbols of sort  $H^n \rightarrow I$ . Then, if  $I$  is a second countable (the topology has a countable base),  $\mathcal{L}$  is separable.

*Proof.* Fix a countable filter of compact neighborhoods of the diagonal of  $I^2$ .  $\square$

## 10. Cauchy complete models

For  $t(x, z)$  a term of sort  $H^{|x|+|z|} \rightarrow I$  we define the formula

$$x \sim_t y = \forall z \ t(x, z) = t(y, z).$$

We also define the type

$$x \sim_I y = \{x \sim_t y : t(x, z) \text{ as above}\}.$$

**Fact 32.** For any  $a = \langle a_i : i < \lambda \rangle$  and  $b = \langle b_i : i < \lambda \rangle$

$$a \sim_I b \Leftrightarrow a_i \sim_I b_i \text{ for every } i < \lambda.$$

*Proof.* Only implication  $\Leftarrow$  requires a proof. Assume  $a_i \sim_I b_i$  for every  $i$ . Let  $|a| = |b| = \lambda$  and assume inductively that

$$\forall y, z \ t(a, y, z) = t(b, y, z)$$

holds for every term  $t(x, y, z)$ , with  $|x| = \lambda$  (universal quantification over the free variables is understood throughout the proof). In particular for any  $a_\lambda$

$$1. \quad \forall z \ t(a, a_\lambda, z) = t(b, a_\lambda, z).$$

As  $a_\lambda \sim_I b_\lambda$  then

$$\forall x, z \ t(x, a_\lambda, z) = t(x, b_\lambda, z)$$

and in particular

$$2. \quad \forall z \ t(b, a_\lambda, z) = t(b, b_\lambda, z).$$

From (1) and (2) we obtain

$$\forall z \ t(a, a_\lambda, z) = t(b, b_\lambda, z).$$

For limit ordinals induction is trivial.  $\square$

Note that the approximations of the formula  $x \sim_I y$  have the form

$$x \sim_{t,D} y = \forall z \langle t(x, z), t(y, z) \rangle \in D$$

for some compact neighborhood  $D$  of  $\Delta$ , the diagonal of  $I^2$ . Hence we define

$$x \sim'_l y = \{x \sim_{t,D} y : t(x, z) \text{ parameter-free term, } D \text{ compact neighborhood of } \Delta\}.$$

If  $t(x, z) = t_1(x, z), \dots, t_n(x, z)$  is a tuple of terms, by  $x \sim_{t,D} y$  we denote the conjunction of the formulas  $x \sim_{t_i,D} y$ . As  $D$  ranges over the compact neighborhoods of  $\Delta$  and  $t(x, z)$  ranges over the finite tuples parameter-free terms. These formulas  $x \sim_{t,D} y$  define a system of entouagages on  $\mathcal{U}^{[x]}$ . We refer to this uniformity and the topology associated as the **l-topology**. Though not needed in the sequel, it is worth mentioning that the l-topology on  $\mathcal{U}^{[x]}$  coincides with the product of the l-topology on  $\mathcal{U}$ . This can be verified by an argument similar to what used in the proof of Fact 32.

We say that  $p(x) \subseteq \mathcal{L}^P(\mathcal{U})$  is **l-invariant** if  $x \sim_l y \rightarrow [p(x) \leftrightarrow p(y)]$ . It is easy to see that all formulas constructed without the use of (ii) of Definon 2 are l-invariant. The following proposition is an immediate consequence of compactness. It corresponds to the Perturbation Lemma [HI, Proposition 5.15].

**Proposition 33.** The following are equivalent for every  $\varphi(x) \in \mathcal{L}^P(\mathcal{U})$

1.  $\varphi(x)$  is l-invariant;
2. for every  $\varphi' > \varphi$  there are a tuple of term  $t$  and a compact neighborhood of  $\Delta$  such that

$$x \sim_{t,D} y \wedge \varphi(x) \rightarrow \varphi'(y).$$

We say that  $p(x)$  is a **Cauchy type** if it is consistent and  $p(x) \wedge p(y) \rightarrow x \sim_l y$ .

We say that a type  $q(x)$  is **finitely satisfiable** in  $M$  if every conjunction of formulas in  $q(x)$  has a solution in  $M$ . This definition is classical but note that, though classically every type over  $M$  is finitely satisfiable in  $M$ , here we can only infer that  $q'(x)$  is finitely satisfiable.

**Lemma 34.** The following are equivalent for every model  $M$

1.  $p(x) \subseteq \mathcal{L}^P(M)$  is an l-invariant Cauchy type;
2.  $p(x) \leftrightarrow a \sim_l x$  for some/any  $a \models p(x)$ ;
3.  $a \sim'_l x$  is finitely satisfiable in  $M$  for some/any  $a \models p(x)$ .

*Proof.* (1 $\Rightarrow$ 2) Let  $a \models p(x)$ . Substituting  $a$  for  $y$  in the definition of Cauchy type we obtain  $p(x) \rightarrow a \sim_l x$ . Similarly, from the definition of l-invariance we obtain  $a \sim_l x \rightarrow p(x)$ .

(2 $\Rightarrow$ 3) By compactness, as  $p'(x)$  is finitely satisfiable in  $M$ .

(3 $\Rightarrow$ 1) Let  $a_{t,D} \in M$  be a realization of  $a \sim_{t,D} x$  as  $D$  ranges over the compact neighborhoods of the diagonal and  $t(x, z)$  over the finite tuples parameter-free terms. Then, by the uniqueness of the limit (up to  $\sim_I$ -equivalence), the type  $p(x)$  containing the formulas  $x \sim_{t,D} a_{t,D}$  is as required by the lemma.  $\square$

We say that a set  $A \subseteq \mathcal{U}$  is **Cauchy complete** if every l-invariant Cauchy type  $p(x) \subseteq \mathcal{L}^P(A)$  is realized by some  $c \in A^{[x]}$ .

**Fact 35.** Let  $M$  be a model that is positively  $\lambda$ -saturated for some  $\lambda > |\mathcal{L}|$ . Then  $M$  is Cauchy complete.

*Proof.* Let  $p(x) \subseteq \mathcal{L}^P(M)$  be an l-invariant Cauchy type. Pick any  $a \models p(x)$ . By Lemma 34,  $p(x) \leftrightarrow a \sim_l x$ . For every formula  $\varphi(x)$  in the type  $a \sim_l x$  and every  $\varphi' > \varphi$  pick some  $\psi(x) \in p$  such that  $\psi(x) \rightarrow \varphi'(x)$ . There are  $|\mathcal{L}|$  many formulas in  $a \sim_l x$ . Then by saturation the formulas  $\psi(x)$  we picked above have a common solution  $b$  in  $M$ . Then  $b \sim_l a$  and, by invariance,  $b \models p(x)$ .  $\square$

It is clear from the proof that when  $\mathcal{L}$  is separable it suffices to require  $\lambda > \omega$ .

### 11. Example: metric spaces

We discuss a simple example. Let  $I$  be  $\mathbb{R}^+ \cup \{0, \infty\}$ , with the topology that makes it homeomorphic to the unit interval. Let  $M, d$  is a metric space. Let  $L_H$  contain symbols for functions  $M^n \rightarrow M$  that are uniformly continuous. Let  $\mathcal{L}$  contain a symbol for  $d$  and possibly for some functions of  $M^n \rightarrow I$  that are uniformly continuous w.r.t. the metric  $d$ .

Let  $\langle M, I \rangle$  be the structure that interprets the symbols of the language as natural.

Let  $\mathcal{U}$  be a monster model that is an  $\mathcal{L}^P$  elementary extension of  $M$ . Clearly,  $d$  does not define a metric on  $\mathcal{U}$  as there are pairs of elements at infinite distance. However, when restricted to a ball of finite radius,  $d$  defines a pseudometric on  $\mathcal{U}$ . Therefore the notion of convergent sequence makes perfectly sense in  $\mathcal{U}$ . As all functions have been required to be uniformly continuous, it is immediate that  $x \sim_1 y$  is equivalent to  $d(x, y) = 0$ .

**Fact 36.** Let  $\mathcal{U}$  be as above. Then for every model  $N$  the following are equivalent for every  $a \in \mathcal{U}$

1.  $p(x) = \mathcal{L}^P\text{-tp}(a/N)$  is a Cauchy type;
2. there is a sequence  $\langle a_i : i \in \omega \rangle$  of elements of  $N$  that converges to  $a$ .

*Proof.* (2 $\Rightarrow$ 1) Let  $\langle \varepsilon_i : i \in \omega \rangle$  be a sequence of reals that converges to 0 and such that  $d(a_i, a) \leq \varepsilon_i$  for every  $i \in \omega$ . Then the formulas  $d(a_i, x) \leq \varepsilon_i$  are in  $p(x)$ . Then every element realizing  $p(x)$  is at distance 0 from  $a$ . Therefore  $p(x) \rightarrow a \sim_1 x$ .

(1 $\Rightarrow$ 2) As  $p(x)$  is Cauchy type,  $p(x) \rightarrow a \sim_1 x$ . Then  $p'(x) \rightarrow d(a, x) < 2^{-i}$  for all  $i$ . By compactness (see Fact 22) there are formulas  $\varphi_i(x) \in p$  such that  $\varphi'_i(x) \rightarrow d(a, x) < 2^{-i}$  for some  $\varphi'_i > \varphi_i$ . By  $\mathcal{L}^P$ -elementarity there is an  $a_i \in N$  such that  $\varphi'(a_i)$ . As  $d(a, a_i) < 2^{-i}$  for all  $i$ , the sequence  $\langle a_i : i \in \omega \rangle$  converges to  $a$ .  $\square$

Danger after this point

## 12. Elimination of quantifiers

Let  $T$  be a positive theory. We say that  $T$  has (approximate) elimination of quantifiers if the quantifier-free positive formulas are dense modulo  $T$ , see Definition 7.

The following fact is routinely proved by back-and-forth.

**Fact 37.** The following are equivalent

1.  $T$  has elimination of quantifiers;
2. every finite partial embedding  $k : M \rightarrow N$  between models of  $T$  is an approximate p-elementary map;
3. for every finite partial embedding  $k : M \rightarrow N$  between positively  $\omega$ -saturated models of  $T$ , and for every  $b \in M$  there is a  $c \in N$  such that  $k \cup \{ \langle b, c \rangle \} : M \rightarrow N$  is also a partial embedding.

## 13. Pseudofinite randomizations

Let  $T$  be a complete first-order theory of signature  $L$  with an infinite model. Let  $\mathcal{U}$  be a model of  $T$ . Let  $\Omega$  be a finite set. We denote by  $\mathcal{U}^\Omega$  the set of functions  $\Omega \rightarrow \mathcal{U}$ . The elements of  $\mathcal{U}^\Omega$  are denoted by letters decorated with a circumflex accent  $\hat{a}, \hat{b}$ , etc. The value of  $\hat{a}$  at  $\omega \in \Omega$  is denoted by  $a_\omega$ . We now define models of the form  $\langle \mathcal{U}^\Omega, I \rangle$ , where  $I$  is the real interval  $[0, 1]$  with the usual topology.

The language  $L_H$  is empty. The language  $\mathcal{L}$  contains functions of sort  $H^{|x|} \rightarrow I$ , one for each formula  $\varphi(x) \in L$ . These are denoted by  $\text{Pr}\varphi(\hat{x})$ . Variables of sort  $H$  are decorated with a circumflex accent. The interpretation of the function symbol  $\text{Pr}\varphi(\hat{x})$  is

$$\text{Pr}(\varphi(\hat{a})) = \frac{\#\llbracket \varphi(\hat{a}) \rrbracket}{\#\Omega},$$

where by  $\#$  denotes the finite cardinality, and

$$\llbracket \varphi(\hat{a}) \rrbracket = \{ \omega \in \Omega : \mathcal{U} \models \varphi(a_\omega) \}.$$

The pseudofinite randomization of  $T$  is the positive theory

$$T^{\text{pfr}} = \left\{ \varphi \in \mathcal{L}^P : \langle \mathcal{U}^\Omega, I \rangle \models \varphi \text{ for all sufficiently large finite set } \Omega \right\}$$

In this section we prove that  $T^{\text{pfr}}$  is a complete theory with elimination of quantifiers.

**Lemma 38.** Let  $k : M \rightarrow N$  be a finite partial embedding between positively  $\omega$ -saturated models of  $T^{\text{pfr}}$ . Then for every  $\hat{b} \in M$  and there is a  $\hat{c} \in N$  such that  $k \cup \{ \langle \hat{b}, \hat{c} \rangle \} : M \rightarrow N$  is an  $\mathcal{L}^P$ -partial embedding.

*Proof.* Let  $\hat{a}$  be an enumeration of  $\text{dom}k$ . Let  $p(\hat{x}, \hat{z})$  be set of formulas of the form  $\gamma = \text{Pr}\varphi(\hat{x}, \hat{z})$ , for some  $\gamma \in I$ , that hold in  $M, \hat{b}, \hat{a}$ . Note that  $p(\hat{x}, \hat{z})$  implies the atomic type of  $\hat{b}, \hat{a}$  in  $M$ . Therefore it suffices to show that  $p(\hat{x}, k\hat{a})$  is finitely consistent in  $N$ .

Pick a finite set of these formulas, say  $\gamma_i = \text{Pr}\varphi_i(\hat{x}, \hat{z})$ , for  $i < n$ . We may assume that the formulas  $\varphi_i(x, z)$  define a partition of  $\mathcal{U}^{[x, z]}$ . By the saturation of  $N$ , it suffices to prove that for every  $\varepsilon > 0$  there is a  $\hat{c} \in N$  such that

$$\gamma_i =_{\varepsilon} \text{Pr}\varphi_i(\hat{c}, k\hat{a}) \quad (\alpha =_{\varepsilon} \beta \text{ is a shorthand for } |\alpha - \beta| \leq \varepsilon)$$

is true in  $N$  for all  $i < n$ .

Some preliminary work is required. For each  $J \subseteq n$  define the following  $L$ -formulas

$$\xi_J(z) = \bigwedge_{i \in J} \exists x \varphi_i(x, z) \wedge \bigwedge_{i \in n \setminus J} \neg \exists x \varphi_i(x, z)$$

These formulas  $\xi_J(z)$  partition  $\mathcal{U}^{|\mathcal{Z}|}$ . For  $J \subseteq n$  let  $\alpha_J \in I$  be such that  $p(\hat{x}, \hat{z})$  contains the formula

$$2. \quad \alpha_J = \Pr(\xi_J(\hat{z}))$$

Let  $\mathcal{J} = \{J \subseteq n : \alpha_J \neq 0\}$ . When  $J \in \mathcal{J}$ , there are some  $\beta_{i,J} \in I$  such that

$$3. \quad \beta_{i,J} = \Pr(\varphi_i(\hat{x}, \hat{z}) \mid \xi_J(\hat{z})).$$

are consequence of  $p(\hat{x}, \hat{z})$ . As the formulas  $\varphi_i(x, z)$  define a partition, the  $\beta_{i,J}$  add up to 1 for any fixed  $J$ . Note that  $\beta_{i,J} = 0$  for  $i \notin J$ . Clearly, have that

$$4. \quad \gamma_i = \sum_{J \in \mathcal{J}} \beta_{i,J} \alpha_J.$$

It is plain that for  $i \in J$  the following is a consequence of  $p(\hat{x}, \hat{z})$

$$5. \quad 1 = \Pr(\exists x \varphi_i(x, \hat{z}) \mid \xi_J(\hat{z}))$$

Now we prove that (2) & (5)  $\Rightarrow$  (1) holds in  $\mathcal{U}^\Omega$  when  $\Omega$  large enough (larger than  $n/\varepsilon$  suffices). Strictly speaking, this implication is not a positive formula, but the reader can easily verify that a suitable approximation of (2) and (5) suffices.

Let  $\hat{a}' \in \mathcal{U}^\Omega$  satisfy (2) and (5) for every  $i \in J \subseteq n$ . We define  $\hat{c}' \in \mathcal{U}^\Omega$  such that

$$\mathcal{U}^\Omega \models \beta_{i,J} =_\varepsilon \Pr(\varphi_i(\hat{c}', \hat{a}') \mid \xi_J(\hat{a}')).$$

We may define  $\hat{c}'$  separately in each event  $\llbracket \xi_J(\hat{a}') \rrbracket$ . Partition  $\llbracket \xi_J(\hat{a}') \rrbracket$  into events  $E_i \subseteq \Omega$ , for  $i \in J$ , such that  $\#E_i / \#\Omega =_\varepsilon \beta_{i,J}$ . Then define  $\hat{c}'_\omega$  for  $\omega \in E_i$  to be any witness of  $\exists x \varphi_i(x, \hat{a}'_\omega)$ . By (5), we can always find such a witness.

Finally, by (4), we deduce

$$\mathcal{U}^\Omega \models \gamma_i =_\varepsilon \Pr(\varphi_i(\hat{c}', \hat{a}')).$$

As  $\hat{k}\hat{a}$  satisfy (2) and (5), we conclude that some  $\hat{c} \in N$  satisfy (1). □

Now, from Fact 37 we obtain that  $T^{\text{pfr}}$  has elimination of quantifiers. Completeness follows.

**Corollary 39.** The theory  $T^{\text{pfr}}$  is complete and has elimination of quantifiers.

## 14. Stability

A partitioned formula  $\varphi(x; z) \in \mathcal{L}^P$  is stable if there is no sequence  $\langle a_i; b_i : i < \omega \rangle$  and no  $\tilde{\varphi} \perp \varphi$  such that for every  $i, j < \omega$

$$i < j \Rightarrow \varphi(a_i; b_j)$$

$$i > j \Rightarrow \tilde{\varphi}(a_i; b_j)$$

Using the terminology of [Hr],  $\varphi(x; z)$  is stable if it is stably separated from all  $\tilde{\varphi} \perp \varphi$ .

Note that by compactness if  $\varphi(x; z)$  and  $\tilde{\varphi} \perp \varphi$  are stably separated then there is a maximal length  $m$  of a sequence  $\langle a_i; b_i : i < m \rangle$  such that (1) and (2) above.
